RE: Filing of Patent Application  
**"EXPRESS MAIL" LABEL NUMBER: EL043440129US**  
Our File: B208-1021

Dear Sir:

Enclosed for filing is a patent application of Yoshihiro Saga for an IMAGE PROCESSING APPARATUS, IMAGE PROCESSING METHOD AND RECORDING MEDIUM, the application comprising a Specification of 29 pages; 40 numbered Claims, including 18 Independent numbered Claims; 5 sheets of Formal Drawings (Figures 1-5); an Abstract and our check in the amount of \$2,290.00 in payment of the filing fee, which has been calculated as follows: \$760.00 base filing fee; \$1,170.00 for 15 Independent claims in excess of three and \$360.00 for 20 Dependent claims in excess of twenty.

A "Combined Declaration and Power of Attorney for Patent Application" will be filed at a later date.

Claim will be made under 35 U.S.C. § 119 for the benefit of the filing date of Japanese Patent Application No. Hei 10-042365 (filed February 24, 1998), a certified copy of which will be filed in due course.

Authorization is given for the charging of any further fee for effecting filing to our Deposit Account 18-1644.

Respectfully submitted

TITLE OF THE INVENTION

IMAGE PROCESSING APPARATUS, IMAGE PROCESSING METHOD AND  
RECORDING MEDIUM

## BACKGROUND OF THE INVENTION

### Field of the Invention

The present invention relates to an image processing apparatus, an image processing method and a computer-readable recording medium or the like, and, more particularly, to an image processing apparatus, an image processing method and a recording medium which are suitable for application to an electronic camera or the like.

### Description of Related Art

Fig. 1 is a block diagram schematically showing the construction of a general digital electronic camera. In the digital electronic camera shown in Fig. 1, a CPU 102 (made of a microprocessor) serves to control the entire system of the digital electronic camera. A DRAM 103 is a memory element called a dynamic RAM (hereinafter referred to as the DRAM) into or from which to write or read image data, camera system programs, work data for the CPU 102 and the like. The DRAM 103 needs to perform an operation called refresh by a predetermined number of times for a predetermined time period so that the DRAM 103 can retain the contents stored therein. A block 104 is a DRAM access circuit for converting the signal outputted from the CPU 102 into a DRAM control signal. A refresh signal generating circuit 106 generates a refresh signal by producing a pulse to be outputted to a RAS (row address strobe) clock line and CAS (column address strobe) clock line which constitute DRAM control lines.

An image pickup circuit 107 is a circuit for converting an image picked up by a CCD image pickup element (not shown) into digital image data and recording the digital image data on the DRAM 103. An image display circuit 108 is a circuit for transferring image data from the DRAM 103 to a liquid crystal display panel, or converting the image data into a video signal and outputting the video signal to an external video output. An image compressing/expanding circuit 109 is a circuit for compressing image data to reduce the amount of information thereof or expanding compressed image data into data having the amount of information that is equivalent to the amount of information of the original image data. A vertical addition mixing circuit 110 is a circuit for adding vertically adjacent lines together to enable video processing of image data for two fields which are outputted from an interlaced CCD image pickup element. An image processing circuit 111 is a circuit for performing the processing of changing a size including the aspect ratio of image data on the DRAM 103, rotating an image, or changing the position of an image in the DRAM 103. A DRAM bus 113 includes a data bus, a DRAM address bus and the DRAM control lines.

The operation of the digital electronic camera shown in Fig. 1 will be described below.

First of all, the image pickup operation of the digital electronic camera will be described below. Image data formed on the CCD image pickup element is read from the

image pickup circuit 107 and is temporarily recorded in the DRAM 103. Then, the vertical addition mixing circuit 110 adds together vertically adjacent lines of the image data on the DRAM 103, and again records the result in the DRAM 103. Then, the image pickup circuit 107 converts the added image data stored in the DRAM 103 into luminance color-difference image data, and again records the result in the DRAM 103. The image processing circuit 111 optimizes the aspect ratio of the luminance color-difference image data. Finally, the image data is compressed by the image compressing/expanding circuit 109, and the picked-up image is recorded as a file on a recording medium (not shown) via the DRAM bus 113.

The image display operation of the digital electronic camera will be described below. First of all, an image file is read from the recording medium by the image compressing/expanding circuit 109, and is expanded into image data in the DRAM 103. The image display circuit 108 reads the image data from the DRAM 103, and outputs the image data to a monitor (not shown). Thus, the image display operation is achieved.

To normally effect the above-described image pickup and display processing, it is necessary that the DRAM 103 be correctly refreshed in the aforesaid processing cycle and that use rights to the data bus or the DRAM 103 be correctly assigned to each image processing, refresh and the CPU 102.

The DRAM 103 needs to perform an operation called refresh by not less than a predetermined number of times for

a predetermined time period. It is assumed herein that the DRAM 103 needs 1,024 refreshes per 128 msec (milliseconds).

However, the image pickup circuit 107 and the image display circuit 108 operate at horizontal and vertical periods. If refresh is performed during an image pickup operation, the image pickup operation is interrupted during the refresh. This leads to the problem that a picked-up image partly lacks data and no correct image can be obtained.

To avoid this problem, the refresh of the DRAM 103 is performed during the blanking periods of an image signal in each of an image pickup operation and an image display operation. The image pickup circuit 107 outputs a horizontal synchronizing signal. Several-microsecond periods before and after the horizontal synchronizing signal are horizontal blanking periods, during which data read from the CCD image pickup element do not appear. During such a horizontal blanking period, the DRAM 103 is refreshed because the image pickup circuit 107 does not need to record data in the DRAM 103.

When the horizontal synchronizing signal is "1", the refresh signal generating circuit 106 generates a refresh signal of one cycle and outputs this refresh signal to both the RAS and CAS clock lines of the DRAM bus 113. It is assumed here that the period of the horizontal synchronizing signal outputted from the image pickup circuit 107 is 85  $\mu$ sec (microseconds). If one refresh is performed each time one horizontal synchronizing signal is outputted,

1,506 refreshes per 128 msec are performed. This satisfies the prescribed condition of the DRAM 103, i.e., 1,024 refreshes per 128 msec.

The horizontal synchronizing signal is coupled to the hold request input of the CPU 102. While the CPU 102 is receiving the horizontal synchronizing signal, the CPU 102 temporarily stops its operation to avoid access to the DRAM 103 during refresh.

The image display circuit 108 operates in synchronism with clocks and horizontal synchronizing signals outputted from the image pickup circuit 107. The image display circuit 108 starts reading display image data several microseconds after the reception of a horizontal synchronizing signal. Assuming that the number of horizontal data of a picked-up image is equal to the number of horizontal data of a display image, the display of one horizontal line is completed before the next horizontal synchronizing signal appears. Since refresh during an image display operation is performed in synchronism with the horizontal synchronizing signal similarly to refresh during an image pickup operation, the refresh during the image display operation is performed during the horizontal blanking periods thereof.

When the image compressing/expanding circuit 109 receives a compression command, the image compressing/expanding circuit 109 compresses the data stored in the DRAM 103 into a predetermined size. The time period required for such compression processing ranges from several

hundred milliseconds to several seconds according to image sizes. It is, therefore, necessary to interrupt the compression processing and refresh the DRAM 103 at intervals of a predetermined time period.

When the horizontal synchronizing signal becomes "1", the refresh signal generating circuit 106 causes the DRAM 103 to start refreshing and outputs a signal indicating that refresh is being performed. When the image compressing/expanding circuit 109 receives this signal, the image compressing/expanding circuit 109 interrupts its processing. During this time, the refresh signal generating circuit 106 outputs a refresh signal to the DRAM 103. If the horizontal synchronizing signal again becomes "0", the signal indicating that refresh is being performed again becomes "0" and the image compressing/expanding circuit 109 restarts the compression processing.

Similarly to the image compressing/expanding circuit 109, the vertical addition mixing circuit 110, the image processing circuit 111 and other image processing circuits operate while interrupting their processing during refresh.

However, the above-described general digital electronic camera has the following problems.

During the operation of a process such as the above-described image processing, the CPU 102 is held and temporarily stops its operation, so that the CPU 102 is not able to perform any operation other than the process. For example, during image compression, the CPU 102 is not able

to perform the processing of displaying characters such as "COMPRESSING" on a liquid crystal display panel or the processing of blinking a system busy indicator lamp which indicates that it is impossible to start an image pickup operation.

In addition, since the unit time of refresh is one horizontal blanking period, refresh is performed by the number of times which is greater than the actually necessary number of times. In the aforesaid example, 1,506 refreshes per 128 msec are performed, which are approximately 1.5 times as large as the actually necessary number of refreshes per unit time, i.e., 1,024 refreshes per 128 msec. As a result, power consumption increases. Particularly during sleep, since the consumption of power due to refresh occupies a large proportion of the energy consumption of the entire camera, the above-described fact is not preferable.

Furthermore, since each of the image compressing/expanding circuit 109, the vertical addition mixing circuit 110 and the image processing circuit 111 receives refresh requests by a large number of times, the frequency with which its process is interrupted becomes higher, and the processing time period of the process becomes longer. This impairs the operability of the digital electronic camera.

During sleep or image display, since no image pickup operation needs to be performed, it is preferable to stop the supply of power to the image pickup circuit 107. However, in the above-described example, since refresh

timing is generated on the basis of the operation of the image pickup circuit 107, it is impossible to stop the image pickup circuit 107 in any situation. Accordingly, it is impossible to achieve a sufficient reduction in power consumption.

#### BRIEF SUMMARY OF THE INVENTION

It is, therefore, an object of the present invention to solve the above-described problems.

Another object of the present invention is to provide an image processing apparatus and method as well as a computer-readable recording medium all of which are capable of reliably executing various kinds of image processing while reliably performing a refresh operation.

To achieve the above object, in accordance with one aspect of the present invention, during the execution of a refresh process for storage means which stores image data, a first process using the storage means and a second process using the storage means, access to the storage element is arbitrated so that the first process takes priority over the refresh process and the refresh process takes priority over the second process.

Another object of the present invention is to provide an image processing apparatus and method as well as a computer-readable recording medium all of which are capable of reducing the refresh rate of storage means to the minimum necessary rate to reduce power consumption and to enhance the speeds of other processes.

To achieve the above object, in accordance with another aspect of the present invention, during the execution of a refresh process for refreshing storage means which stores image data and a process for processing the image data by performing writing of the image data into the storage means or reading of the image data from the storage means, whether to synchronize the refresh process with an image is specified according to the contents of the image data processing process.

Another object of the present invention is to provide an image processing apparatus and method as well as a computer-readable recording medium all of which enable a CPU or the like to efficiently execute image processing as well as processing other than refresh.

To achieve the above object, in accordance with another aspect of the present invention, during switching from a refresh process for refreshing storage means which store image data to a process for processing image data by performing writing of the image data into the storage means or reading of the image data from the storage means, another operation is controlled by using the storage means.

The above and other objects, features and advantages of the present invention will become apparent from the following detailed description of preferred embodiments of the present invention, taken in conjunction with the accompanying drawings.

#### BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

Fig. 1 is a block diagram schematically showing the construction of a general digital electronic camera.;

Fig. 2 is a block diagram schematically showing the construction of a digital electronic camera according to one embodiment of the present invention;

Fig. 3 is a block diagram showing the essential portion of a first type of process circuit incorporated in the electronic camera shown in Fig. 2;

Fig. 4 is a block diagram showing the essential portion of a second type of process circuit incorporated in the electronic camera shown in Fig. 2; and

Fig. 5 is a diagram showing the state transition of a bus arbitrating circuit in the electronic camera shown in Fig. 2.

#### DETAILED DESCRIPTION OF THE INVENTION

A preferred embodiment of the present invention will be described below in detail with reference to the accompanying drawings.

Fig. 2 diagrammatically shows the construction of a digital electronic camera according to the preferred embodiment of the present invention.

The digital electronic camera shown in Fig. 2 includes a DRAM bus arbitrating circuit 101 for arbitrating accesses to a DRAM bus by a CPU 102, a process circuit and a refresh circuit both of which will be described later, a refresh timing counter 105 for generating one pulse at intervals of a predetermined time period, OR circuits 112,

115 and 116, a refresh holding counter 114, the CPU 102 and other constituent elements 103, 104, 106 to 111 and 113.

Since the constituent elements 102 to 104, 106 to 111 and 113 have been previously described with reference to Fig. 1, the description thereof is omitted for the sake of simplicity. The DRAM 103, in which a program for the CPU 102 is also stored, constitutes a computer-readable storage medium according to the present invention.

The operation of the digital electronic camera according to the preferred embodiment of the present invention will be described below. The digital electronic camera is arranged to execute processes including an image pickup process, an image display process, an image compressing/expanding process, a vertical addition mixing process and an image processing process. First of all, the operations of the respective processes and the operation of the DRAM bus arbitrating circuit 101 will be described below. Each of the process circuits 107 to 111 is classified into a process circuit of the type A shown in Fig. 3 or a process circuit of the type B shown in Fig. 4.

Referring to the process circuit of the type A shown in Fig. 3, when a command processing circuit 301 receives a process start command from the CPU 102, the command processing circuit 301 generates a process request signal P\_REQ indicative of "1". This process request signal P\_REQ passes through the OR circuit 112 and is inputted into the DRAM bus arbitrating circuit 101. When the DRAM bus arbitrating circuit 101 receives the process request signal

P\_REQ indicative of "1", the DRAM bus arbitrating circuit 101 requests a refresh or a CPU access to release an access right to the DRAM bus 113. If neither the refresh nor the CPU access has occurred, the DRAM bus arbitrating circuit 101 directly proceeds to the next step. Although not shown in Fig. 2, a connection line for transmission or reception of commands is disposed between the CPU 102 and each of the circuits 107 to 111.

If the DRAM bus 113 is released, the DRAM bus arbitrating circuit 101 gives a DRAM bus use right to a process circuit 302 and then generates a signal P\_ACK indicative of "1" which means that the DRAM bus use right is given to the process circuit 302. When the process circuit 302 receives the signal P\_ACK indicative of "1", the process circuit 302 starts a predetermined process. Upon the completion of the predetermined process, the process circuit 302 resets the process request signal P\_REQ to "0". When the DRAM bus arbitrating circuit 101 receives the process request signal P\_REQ indicative of "0", the DRAM bus arbitrating circuit 101 returns to a standby state and waits until a DRAM access, a refresh or a process by the CPU 102 again requests a DRAM bus use right.

The process circuit of this type A, once it starts a process, executes the process in preference to any request from another circuit. Each of the image pickup circuit 107 and the image display circuit 108 is realized as the process circuit of the type A. When an image pickup operation or an image display operation is to be started, the corresponding

one of the image pickup circuit 107 and the image display circuit 108 outputs a process request signal P\_REQ indicative of "1" and acquires an access right to the DRAM bus 113. Upon the completion of the operation of picking up or displaying an image for one line, the corresponding circuit 107 or 108 resets the process request signal P\_REQ to "0" and releases the DRAM bus 113.

Thus, a refresh operation is prevented from being started during the operation of picking up or displaying an image for one line, whereby an image can be picked up or displayed without interruption. A refresh is performed after the release of the DRAM bus 113, i.e., during a horizontal blanking period. The refresh operation will be described later.

The process circuit of the type B shown in Fig. 4 will be described below. When a command processing circuit 401 receives a process start command from the CPU 102, the command processing circuit 401 outputs a signal of "0". In the meantime, when a timer 403 receives a signal VR\_REQ indicative of "1", the timer 403 is reset and starts counting a predetermined time period. While the timer 403 is performing a counting operation, the timer 403 outputs a signal of "0"; otherwise, the timer 403 outputs a signal of "1". The output of the command processing circuit 401 and the output of the timer 403 are ANDed by an AND circuit 404, and the obtained logical product is outputted as a process request signal P\_REQ. Thus, the process circuit of the type B, when it receives a start command, outputs the process

request signal P\_REQ indicative of "1", but if the process circuit receives a signal of "1" at the terminal VR\_REQ (to be described later) which interlocks with a refresh request, the process circuit of the type B outputs a process request signal P\_REQ indicative of "0" during a predetermined time period which corresponds to a value written into a time setting register 405 by the CPU 102.

So long as the output of the timer 403 is not "0", when the command processing circuit 401 receives a process start command from the CPU 102, the process circuit of this type B generates a process request signal P\_REQ indicative of "1". This signal P\_REQ passes through the OR circuit 112 and is inputted into the DRAM bus arbitrating circuit 101. When the DRAM bus arbitrating circuit 101 receives the process request signal P\_REQ indicative of "1", the DRAM bus arbitrating circuit 101 requests a refresh or a CPU access to release an access right to the DRAM bus 113. If neither the refresh nor the CPU access has occurred, the DRAM bus arbitrating circuit 101 directly proceeds to the next step.

If the DRAM bus 113 is released, the DRAM bus arbitrating circuit 101 gives a DRAM bus use right to a process circuit 402 and then generates a signal P\_ACK indicative of "1" which means that the DRAM bus use right is given to the process circuit 402. When the refresh timing counter 105 which will be described later outputs a signal of "1" to the refresh holding counter 114, the refresh holding counter 114 receive this signal indicative of "1" and outputs a signal R\_REQ indicative of "1". As will be

described later, when the refresh timing counter 105 outputs the signal of "1", the timer 403 is reset, and starts a counting operation and outputs a signal of "0".

Accordingly, the process request signal P\_REQ is reset to "0", and the process circuit 402 temporarily stops.

When the DRAM bus arbitrating circuit 101 determines that the signal R\_REQ is "1" and the signal P\_REQ is "0", the DRAM bus arbitrating circuit 101 gives the DRAM bus use right to refresh processing and then outputs a refresh instruction signal to the refresh signal generating circuit 106. The refresh signal generating circuit 106 outputs a refresh signal to the DRAM bus 113 and refreshes the DRAM 103.

Even after the refresh of the DRAM 103 has been completed, the timer 403 continues to output a signal of "0" until a predetermined time period elapses. Accordingly, the process request signal P\_REQ remains "0". During this time, the DRAM bus 113 remains released. Accordingly, the CPU 102 is allowed to operate while using the DRAM bus 113.

When the timer 403 counts up the predetermined time period, the process request signal P\_REQ is again set to "1". When the process circuit receives a signal P\_ACK indicative of "1", the process circuit restarts its process. If the process circuit completes its process operation, the command processing circuit 401 outputs a signal of "0" so that the process request signal P\_REQ is reset to "0".

Each of the image compressing/expanding circuit 109, the vertical addition mixing circuit 110 and the image

processing circuit 111 has a comparatively long processing time period and can be arranged so that even if its processing is interrupted at an intermediate step, the result of the processing is not affected by such interruption. For this reason, each of the circuits 109, 110 and 111 is arranged as the process circuit of the type B. The set value of the time setting register 405 in each of the circuits 109, 110 and 111 will be described later.

The refresh operation will be described below. By way of example, it is assumed that the DRAM 103 used in the present embodiment needs to be refreshed by 1,024 times for 128 msec. Referring to Fig. 2, the refresh timing counter 105 generates one pulse at intervals of 125  $\mu$ sec. The refresh holding counter 114 is an up/down counter capable of counting up to 16. When the refresh holding counter 114 receives one pulse from the refresh timing counter 105, the refresh holding counter 114 increments its count value by one, and if the DRAM 103 is refreshed once, the refresh holding counter 114 decrements the count value by one. When the count value is not less than "1", the refresh holding counter 114 outputs a signal R\_REQ indicative of "1".

In addition, the DRAM bus arbitrating circuit 101 is arranged to output a signal R\_ACK indicative of "1" to the refresh signal generating circuit 106 when the count value of the refresh holding counter 114 is not less than "1" and the DRAM bus 113 is not occupied by another process. The operation of outputting the signal R\_ACK indicative of "1" is repeated until the count value of the refresh holding

counter 114 reaches "0".

Thus, such refresh is performed once per 125  $\mu$ sec, but even if the DRAM bus 113 is occupied for a time period longer than 125  $\mu$ sec by the process circuit of the type A, the refresh is performed once per 125  $\mu$ sec as long as the time period is shorter than 2,000  $\mu$ sec (= 125  $\mu$ sec  $\times$  16). This time period is sufficiently long if one horizontal synchronizing period of an image pickup or display operation is 85  $\mu$ sec. Thus, the prescribed condition of the DRAM 103, i.e., 1,024 refreshes per 128 msec, is satisfied, and the system of the digital electronic camera can operate stably.

Assuming that the DRAM 103 needs to be refreshed by 1,024 time for 16.4 msec, the pulse generation period of the refresh timing counter 105 needs to be 16  $\mu$ sec. Thus, 1,024 refreshes per 16.4 msec are achieved.

It is assumed here that one horizontal synchronizing period of an image pickup or display operation is 85  $\mu$ sec. The upper limit of the refresh holding counter 114 needs to be determined to satisfy:

$$z > x/y, \quad \dots \quad (1)$$

where x represents the horizontal synchronizing period, y represents the pulse generation period of the refresh timing counter 105, and z represents the upper limit of the refresh holding counter 114. If the upper limit of the refresh holding counter 114 is selected to be "16", the maximum occupation time period of the DRAM bus 113 becomes 256  $\mu$ sec. Since this time period is sufficiently longer than the horizontal synchronizing period, the system can operate

stably.

A CPU access operation will be described below.

The CPU 102 has an input terminal HOLDREQ and an output terminal HOLDAK. If a signal of "1" is inputted to the input terminal HOLDREQ, the CPU 102 temporarily stops its operation, and outputs a signal of "1" at the output terminal HOLDAK to indicate that the CPU 102 has stopped the operation. Then, if a signal of "0" is inputted to the input terminal HOLDREQ, the CPU 102 outputs a signal of "0" at the output terminal HOLDAK and restarts the operation. A signal line HOLDREQ of the DRAM bus arbitrating circuit 101 is connected to the input terminal HOLDREQ of the CPU 102. Before a process or a refresh is started, the DRAM bus arbitrating circuit 101 outputs a signal of "1" to the input terminal HOLDREQ of the CPU 102 and temporarily stops the CPU 102. If neither the process nor the refresh needs to be performed, the DRAM bus arbitrating circuit 101 outputs a signal of "0" to the input terminal HOLDREQ and enables the CPU 102 to perform the operation.

The DRAM bus arbitrating circuit 101 which is responsible for the above-described control will be described below. Fig. 5 is a state transition diagram showing the internal state transition of the DRAM bus arbitrating circuit 101. The DRAM bus arbitrating circuit 101 is arranged to start any of a refresh, a CPU access and a process in a state "a", and bring them to an end in the state "a".

First of all, the state transition of the DRAM bus

arbitrating circuit 101 during the process operation will be described below. The DRAM bus arbitrating circuit 101, when it is idle, is in the state "a" shown in Fig. 5. If the process circuit receives a command and a process request signal P\_REQ indicative of "1" is outputted to the DRAM bus arbitrating circuit 101, the DRAM bus arbitrating circuit 101 transitions to a state "b". In the state "b", the DRAM bus arbitrating circuit 101 outputs a signal of "1" to the input terminal HOLDREQ of the CPU 102. When the CPU 102 receives the signal of "1", the CPU 102 temporarily stops the operation and outputs a signal of "1" at the output terminal HOLDAK. When the DRAM bus arbitrating circuit 101 receives the signal of "1", the DRAM bus arbitrating circuit 101 transitions to a state "c" and outputs a signal P\_ACK indicative of "1". The process circuit receives this signal P\_ACK and starts its process processing. When the process circuit completes the process processing, a process request signal P\_REQ indicative of "0" is outputted to the DRAM bus arbitrating circuit 101. In response to this signal P\_REQ, the DRAM bus arbitrating circuit 101 transitions to a state "d". In the state "d", the DRAM bus arbitrating circuit 101 outputs a signal of "0" to the input terminal HOLDREQ of the CPU 102. When the CPU 102 receives this signal, the CPU 102 outputs a signal of "0" at the output terminal HOLDAK and restarts the processing. When the DRAM bus arbitrating circuit 101 receives this signal, the DRAM bus arbitrating circuit 101 transitions to the state "a".

The state transition of the DRAM bus arbitrating

circuit 101 during refresh will be described below. When in the state "a", the DRAM bus arbitrating circuit 101 is in an idle state. If a refresh request signal R\_REQ indicative of "1" is outputted to the DRAM bus arbitrating circuit 101 during the idle state, the DRAM bus arbitrating circuit 101 receives the refresh request signal R\_REQ and transitions to a state "e". When in the state "e", the DRAM bus arbitrating circuit 101 outputs a signal of "1" to the input terminal HOLDREQ of the CPU 102. When the CPU 102 receives this signal, the CPU 102 temporarily stops the operation and outputs a signal of "1" at the output terminal HOLDAK. When the DRAM bus arbitrating circuit 101 receives the signal of "1", the DRAM bus arbitrating circuit 101 transitions to a state "f" and outputs a signal R\_ACK indicative of "1".

When the refresh signal generating circuit 106 receives the signal R\_ACK indicative of "1", the refresh signal generating circuit 106 outputs a refresh pulse for one refresh cycle to the DRAM bus 113 and refreshes the DRAM 103. When one cycle of refresh is completed, the DRAM bus arbitrating circuit 101 outputs a signal R\_ACK indicative of "0" and, at the same time, the count value of the refresh holding counter 114 is decremented by one. Thus, the DRAM bus arbitrating circuit 101 transitions to a state "g". When in the state "g", the DRAM bus arbitrating circuit 101 outputs a signal of "0" to the input terminal HOLDREQ of the CPU 102. In response to this signal, the CPU 102 restarts the operation and outputs a signal of "0" at the output terminal HOLDAK. Thus, the DRAM bus arbitrating circuit 101

transitions to the state "a" and completes the refresh operation. At this time, if the count value of the refresh holding counter 114 is not "0", it indicates that a signal R\_REQ indicative of "0" has been outputted from the DRAM bus arbitrating circuit 101, so that the above-described refresh state transition cycle is again executed.

The operation of the DRAM bus arbitrating circuit 101 during CPU access will be described below. When the DRAM bus arbitrating circuit 101 is in the state "a", the CPU 102 can access the DRAM 103. If the CPU 102 accesses the DRAM 103, the DRAM access circuit 104 outputs a signal C\_REQ indicative of "1" to the DRAM bus arbitrating circuit 101. When the DRAM bus arbitrating circuit 101 receives the signal C\_REQ, the DRAM bus arbitrating circuit 101 transitions to a state "h". Accordingly, during the CPU access, neither a process nor a refresh is activated. When the CPU access is completed, the DRAM access circuit 104 outputs a signal C\_REQ indicative of "1" to the DRAM bus arbitrating circuit 101. When the DRAM bus arbitrating circuit 101 receives the signal C\_REQ, the DRAM bus arbitrating circuit 101 transitions to the state "a" and returns to the idle state.

The above-described operations are summarized below. During the operation of the image pickup circuit 107, while the image pickup circuit 107 is reading one line of image data from a CCD (not shown), the image pickup circuit 107 uses the DRAM bus 113 with the highest priority. Similarly, during the operation of the image display circuit

108, while the image display circuit 108 is outputting one line of image data to a monitor (not shown), the image display circuit 108 uses the DRAM bus 113 with the highest priority. During the blanking periods of an image pickup or display operation, refresh is performed with priority during the first time period, and the CPU 102 accesses the DRAM 103 during the remaining time period.

During the operation of each of the image compressing/expanding circuit 109, the vertical addition mixing circuit 110 and the image processing circuit 111, refresh is performed in preference to their operation. It is to be noted that a time period elapses until these circuits set the process request signal P\_REQ to "1" after the refresh, the time period being equivalent to the difference between the time period set in the time setting register 405 and the time period actually required for the refresh. During such time period, the CPU 102 can access the DRAM 103.

The set value of the time setting register 405 for each of processes to be executed by the image compressing/expanding circuit 109, the vertical addition mixing circuit 110 and the image processing circuit 111 will be described below. By optimizing the set value of the time setting register 405 for each of the circuits 109, 110 and 110, it is possible to optimize the proportion of the operation-enabled time period of each of the circuits 109, 110 and 110 to the operation-enabled time period of the CPU 102.

In the present embodiment, a set value to be written into the time setting register 405 in the vertical addition mixing circuit 110 is selected to be smaller than those to be written into the respective time setting registers 405 of the other circuits 109 and 111. This is because, at the time of vertical addition mixing processing, the CPU 102 needs only to detect whether vertical addition mixing processing has been completed, and the aforesaid set value may be a required minimum value.

However, during image compressing/expanding processing, if characters such as "COMPRESSING" are to be displayed on a display panel (not shown), the set value for the image compressing/expanding circuit 109 needs to be made larger than that for the vertical addition mixing circuit 110 so that the CPU 102 can optimally perform the operation of displaying such characters.

In the case of the image processing circuit 111 as well, the set value of the time setting register 405 may be adjusted in a similar manner. However, if the set value of the time setting register 405 of the image processing circuit 111 is made larger, the average speed of the process of the image processing circuit 111 becomes slower; whereas if the set value is made smaller, the average speed of the process becomes faster. In the present embodiment, characters such as those formed by the CPU 102 are displayed on the display panel during the operation of the image compressing/expanding circuit 109, and the CPU 102 participates in the setting of the processing contents or

the like of the image processing circuit 111. Therefore, the respective set values of the time setting registers 405 of the circuits 109, 110 and 111 are made larger in the order of the circuit 109, the circuit 111 and the circuit 110.

An additional description will be given in connection with the image compressing/expanding circuit 109. The image display circuit 108 outputs a signal of "0" when it is not performing an image display operation or during the blanking periods of the image display operation. This signal is applied to one input terminal of the OR circuit 115. The output of the refresh timing counter 105 is applied to the other input terminal of the OR circuit 115. The output of the OR circuit 115 is connected to an input VR\_REQ of the image compressing/expanding circuit 109.

In this arrangement, when the image display circuit 108 is not in operation, the image compressing/expanding circuit 109 is allowed to operate when no refresh is needed; whereas when the image display circuit 108 is in operation, the image compressing/expanding circuit 109 is allowed to operate only when no refresh request takes place during the blanking periods of an image display operation. Accordingly, it is possible to realize time-division parallel processing of an image display operation and image compressing/expanding processing. If this time-division parallel processing is used, it is possible to smoothly rewrite an image currently displayed on the screen of a monitor with the next different image without stopping

the operation of displaying an image on the monitor. As a matter of course, when the image display circuit 108 is not performing an image display operation, the image compressing/expanding circuit 109 operates as a normal process circuit of the type B. Such an arrangement is also useful for the image processing circuit 111 because the arrangement enables the image processing circuit 111 to perform processing, such as a variation in the size of an image or a rotation of the image on the screen of the monitor, while displaying the image.

According to the present embodiment, in an image pickup or display operation, refresh is performed during only each blanking period so that there is no possibility that an interruption occurs in the image pickup or display operation during one line period. In addition, it is possible to realize time-division processing of both a process which requires a comparatively long processing time period, such as image compression/expansion, vertical addition mixing or image processing, and the access of the CPU 102 to the DRAM 103. This feature enables, for example, the function of blinking a display such as "COMPRESSING" on the monitor during the compression of an image. Furthermore, since the DRAM 103 is refreshed by an optimum number of times, power consumption due to refresh can be minimized and the interruption of the aforesaid processing can be minimized to reduce the entire processing time. Accordingly, it is possible to provide a digital electronic camera of good operability.

In addition, the image display circuit 108 and the image pickup circuit 107 as well as the image display circuit 108 and the image processing circuit 111 can be operated apparently at the same time in a time-division manner, whereby it is possible to realize processing such as the rewriting of data on the monitor or the rotation of an image on the monitor during the display of the image on the monitor.

Furthermore, since no refresh timing is obtained from the image pickup circuit 107, the supply of power to the image pickup circuit 107 can be stopped if no image pickup operation needs to be performed, whereby it is possible to realize a further decrease in power consumption.

As is apparent from the foregoing description, according to the present embodiment, since various kinds of image processing are divided into first processing which can be performed with priority and second processing over which refresh takes priority, it is possible to appropriately effect the various kinds of image processing by using a memory which needs refreshing, such as a DRAM, while reliably refreshing the memory.

Since the first processing is assigned the processing of storing picked-up image data and the processing of displaying the stored image data, it is possible to prevent an interruption in an image pickup or display operation.

Since the second processing is assigned processing which requires a comparatively long processing time period,

for example, compression/expansion of image data, vertical addition and size change, such processing can be performed in a time-division manner, whereby it is possible to provide display during the processing. In addition, since refresh is performed by an optimum number of times, power consumption can be reduced.

In addition, even in the first processing, it is possible to reliably effect refresh during the blanking periods of picked-up image data or display image data.

In addition, since it is possible to effect refresh during blanking periods or respond to a refresh request while performing compressing/expanding processing or image processing, it is possible to effect rewriting or processing of image data on the monitor while displaying an image on the monitor.

In addition, access to a memory by control means such as a CPU can be effected at appropriate timing during each processing.

In addition, since refresh is performed with a counter whose count value increments by one for a predetermined time period and decrements by one for each refresh, it is possible to reliably effect refresh within a required time period.

In other words, in accordance with the present embodiment, since an image pickup or display operation is performed without interruption, an image pickup operation can be completed in a shortest image pickup time period and a high-quality display screen free of noise can be achieved.

Since both a process which requires a comparatively long processing time period, such as image compression/expansion, vertical addition mixing or image processing, and access to a DRAM by a CPU can be executed by time-division processing, it is possible to realize the function of blinking a display such as "COMPRESSING" on the monitor during, for example, the compression of an image.

Power consumption due to refresh can be minimized, and the supply of power to an image pickup circuit can be stopped, whereby it is possible to realize a further decrease in power consumption.

In addition, it is possible to realize processing such as the rewriting of data on the monitor or the rotation of an image on the monitor during the display of the image on the monitor.

As is apparent from the above description, it is possible to provide an apparatus such as a digital electronic camera of good operability.

Furthermore, since the operating time of the CPU is optimally set for each image processing circuit, the average processing time period of each image processing circuit can be reduced, and it is possible to optimize the processing time period of each image processing circuit according to whether the CPU needs to create display data.

CLAIMS

1. An image processing apparatus comprising:  
storage means for storing image data;  
refresh means for performing a refresh operation  
for refreshing said storage means within a predetermined  
time period;  
first and second process means for respectively  
performing their predetermined processes by using said  
storage means; and  
arbitrating means for performing arbitration to  
cause said first process means to perform the predetermined  
process as a priority over the refresh operation and to  
cause said second process means to perform the predetermined  
process while allowing the refresh operation to be performed  
as a priority over the predetermined process.
2. An image processing apparatus according to claim  
1, wherein said first process means includes at least one of  
image pickup means for storing picked-up image data in said  
storage means and display means for displaying the image  
data stored in said storage means.
3. An image processing apparatus according to claim  
1, wherein said second process means includes at least one  
of compressing/expanding means for compressing/expanding the  
image data, adding means for adding together vertical  
adjacent data of the image data, and processing means for

processing the image data.

4. An image processing apparatus according to claim 1, wherein said arbitrating means causes said refresh means to perform the refresh operation during a blanking period of the picked-up image data or the image data to be displayed.

5. An image processing apparatus according to claim 1, wherein said first process means includes display means for displaying the image date stored in said storage means, and, while said second process means is operating, allows the refresh operation to be performed on the basis of a refresh request from said refresh means during a blanking period of the image data to be displayed.

6. An image processing apparatus according to claim 1, further comprising control means for controlling another operation of said image processing apparatus, a control program for said control means being stored in said storage means, said control means accessing said storage means during an idle time period other than a time period during which any of said refresh means and said first and second process means accesses said storage means.

7. An image processing apparatus according to claim 1, wherein said arbitrating means includes counting means for counting up to a predetermined number, said counting means being arranged to increment a count value by one

within the predetermined time period and, each time the refresh operation is performed once, decrement the count value by one, said refresh means performing the refresh operation when the count value is not less than 1.

8. A computer-readable recording medium in which is stored a program for executing:

a storage process for storing image data in storage means;

a refresh process for performing a refresh operation for refreshing the storage means within a predetermined time period;

a first process for performing a predetermined process as a priority over the refresh operation by using the storage means; and

a second process for performing a predetermined process while allowing the refresh operation to be performed as a priority over the predetermined process.

9. A recording medium according to claim 8, wherein said first process includes at least one of an image pickup process for storing picked-up image data in the storage means and a display process for displaying the image date stored in the storage means.

10. A recording medium according to claim 9, wherein said second process includes at least one of a compressing/expanding for compressing/expanding the image

data, an adding process for adding together vertical adjacent data of the image data, and a processing process for processing the image data.

11. A recording medium according to claim 9, wherein said refresh process is performed during a blanking period of the picked-up image data or the image data to be displayed.

12. A recording medium according to claim 8, wherein said first process includes a display process for displaying the image date stored in the storage means, and, while said second process is operating, allows the refresh operation to be performed on the basis of a refresh request during a blanking period of the image data to be displayed.

13. An image processing apparatus comprising:  
storage means for storing image data;  
refresh means for refreshing said storage means;  
a plurality of process means each of which performs writing of image data into said storage means or reading of image data from said storage means; and  
arbitrating means for arbitrating operations of said plurality of process means and an operation of said refresh means.

14. An image processing apparatus according to claim 13, wherein said arbitrating means specifies whether to

synchronize the operation of said refresh means with image data, according to the kind of process executed by each of said plurality of process means.

15. An image processing apparatus according to claim 14, wherein said arbitrating means synchronizes the operation of said refresh means with a horizontal synchronizing signal of the image data while particular process means among said plurality of process means is operating, said particular process means being arranged to perform an image input process or an image output process.

16. An image processing apparatus according to claim 15, wherein said arbitrating means sets a period of the operation of said refresh means to a predetermined period determined on the basis of a characteristic of said storage means while particular process means among said plurality of process means is operating, said particular process means being arranged to perform an image processing process or an image compressing process.

17. An image processing apparatus according to claim 13, further comprising control means for exerting system control over said image processing apparatus by using said storage means, said control means being operated during a transition from a state in which said refresh means operates to a state in which said plurality of process means operate.

18. An image processing apparatus comprising:  
storage means for storing image data;  
refresh means for refreshing said storage means;  
process means for writing image data into said  
storage means or reading image data from said storage means;  
and

control means for controlling another operation of  
said image processing apparatus by using said storage means,  
wherein said control means is operated during a  
transition from a state in which said refresh means operates  
to a state in which said process means operates.

19. An image processing apparatus according to claim  
18, wherein said process means is arranged to perform an  
image input process or an image output process, and said  
refresh means is arranged to operate during a horizontal  
blanking period of image data.

20. An image processing apparatus comprising:  
storage means for storing image data;  
refresh means for refreshing said storage means;  
and  
a plurality of process means each of which  
performs writing of image data into said storage means or  
reading of image data from said storage means,  
wherein a period of an operation of said refresh  
means is switched according to the kind of process executed  
by process means which is operating, among said plurality of

process means.

21. An image processing apparatus according to claim 20, wherein the operation of said refresh means is synchronized with a horizontal synchronizing signal of the image data if the process executed by said process means is an image input process or an image output process.

22. An image processing apparatus according to claim 21, wherein a period of the operation of said refresh means is set to a predetermined period determined on the basis of a characteristic of said storage means if the process executed by said process means is an image processing process or an image compressing process.

23. An image processing apparatus comprising:  
storage means for storing image data;  
refresh means for refreshing said storage means;  
and

process means for performing writing of image data into said storage means or reading of image data from said storage means,

wherein said refresh means is operated during only a blanking period selected from among blanking periods of a synchronizing signal of said image data.

24. An image processing apparatus according to claim 23, wherein an average refresh period of said refresh means

is set to a period determined on the basis of a characteristic of said storage means.

25. An image processing apparatus comprising:

- (a) storage means for storing image data;
- (b) refresh means for refreshing said storage means;
- (c) a plurality of process means each of which performs writing of image data into said storage means or reading of image data from said storage means;
- (d) control means for controlling another operation by using said storage means; and
- (e) arbitrating means for arbitrating access to said storage means so that a period during which to operate said control means and a period during which to operate process means which is operating, among said plurality of process means, is relatively switched therebetween, according to the kind of process means which is operating.

26. An apparatus according to claim 25, wherein said arbitrating means causes said refresh means to perform a predetermined operation, and disables processes of said plurality of process means for a predetermined time period and causes said control means to operate until the end of the predetermined time period after the completion of the predetermined operation of said refresh means.

27. An apparatus according to claim 26, wherein the predetermined time period is determined according to each of

said plurality of process means.

28. An apparatus according to claim 27, wherein each of said plurality of process means has a register for holding a value which corresponds to the predetermined time period, said control means being capable of rewriting said register.

29. An apparatus according to claim 28, wherein said plurality of process means include first process means for reading image data stored in said storage means, in order to display the image data, and a plurality of second process means for varying said image data into different forms, respectively, said arbitrating means being arranged to relatively switch, according to the kind of second process means which is operating, among said plurality of second process means, a period during which to operate said control means and a period during which to operate said second process means which is operating, during a blanking period of image data displayed by said first process means.

30. An image processing method comprising steps of:

- (a) performing a refresh process on storage means which stores image data;
- (b) performing a first process by using the storage means;
- (c) performing a second process by using the storage means; and

(d) arbitrating access to the storage means in such a manner that the first process takes priority over the refresh process and the refresh process takes priority over the second process.

31. An image processing method comprising steps of:

- (a) performing a refresh process on storage means which stores image data;
- (b) processing image data by performing writing of the image data into the storage means or reading of the image data from the storage means; and
- (c) specifying whether to synchronize the refresh process with an image, according to a process content of said image processing step.

32. A computer-readable recording medium in which is stored a program for executing:

- a step of performing a refresh process on storage means which stores image data;
- a step of processing image data by performing writing of the image data into the storage means or reading of the image data from the storage means; and
- a step of specifying whether to synchronize the refresh process with an image, according to a process content of said image processing step.

33. An image processing method comprising steps of:

- (a) performing a refresh process on storage means

which stores image data;

(b) processing image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

(c) controlling another operation by using the storage means; and

(d) executing said control step during switching from said refresh process step to said image data processing step.

34. A computer-readable recording medium in which is stored a program for executing:

a step of performing a refresh process on storage means which stores image data;

a step of processing image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

a step of controlling another operation by using the storage means; and

a step of executing said control step during switching from said refresh process step to said image data processing step.

35. An image processing method comprising steps of:

(a) performing a refresh process on storage means which stores image data;

(b) applying a first process to image data by performing writing of the image data into the storage means

or reading of the image data from the storage means;

(c) applying a second process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means; and

(d) switching a period of the refresh process between when the first process is performed and when the second process is performed.

36. A computer-readable recording medium in which is stored a program for executing:

a step of performing a refresh process on storage means which stores image data;

a step of applying a first process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

a step of applying a second process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means; and

a step of switching a period of the refresh process between when the first process is performed and when the second process is performed.

37. An image processing method comprising steps of:

(a) performing a refresh process on storage means which stores image data;

(b) applying a process to image data by performing writing of the image data into the storage means or reading

of the image data from the storage means; and

(c) performing the refresh process during only a blanking period selected from among blanking periods of an image signal indicative of the image data.

38. A computer-readable recording medium in which is stored a program for executing:

a step of performing a refresh process on storage means which stores image data;

a step of applying a process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means; and

a step of performing the refresh process during only a blanking period selected from among blanking periods of an image signal indicative of the image data.

39. An image processing method comprising steps of:

(a) performing a refresh process on storage means which stores image data;

(b) applying a first process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

(c) applying a second process different from the first process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

(d) controlling another operation of an image processing apparatus by the storage means; and

(e) relatively switching a time period during which to control said other operation and a time period during which to execute the first or second process, according to whether the first process or the second process is being performed.

40. A computer-readable recording medium in which is stored a program for executing:

a step of performing a refresh process on storage means which stores image data;

a step of applying a first process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

a step of applying a second process different from the first process to image data by performing writing of the image data into the storage means or reading of the image data from the storage means;

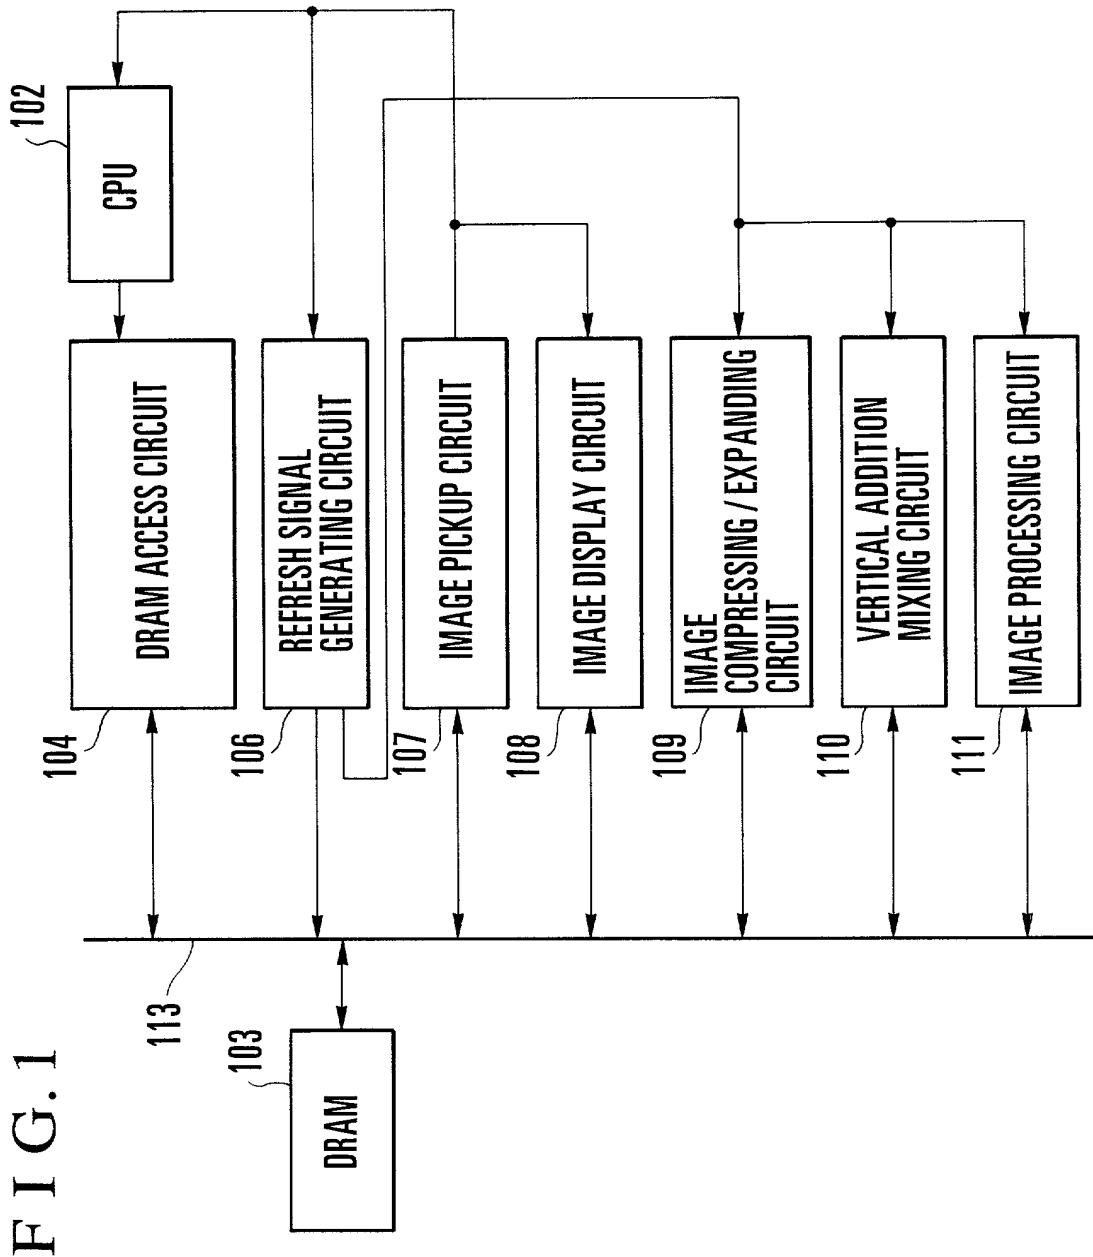

a step of controlling another operation of an image processing apparatus by the storage means; and

a step of relatively switching a time period during which to control said other operation and a time period during which to execute the first or second process, according to whether the first process or the second process is being performed.

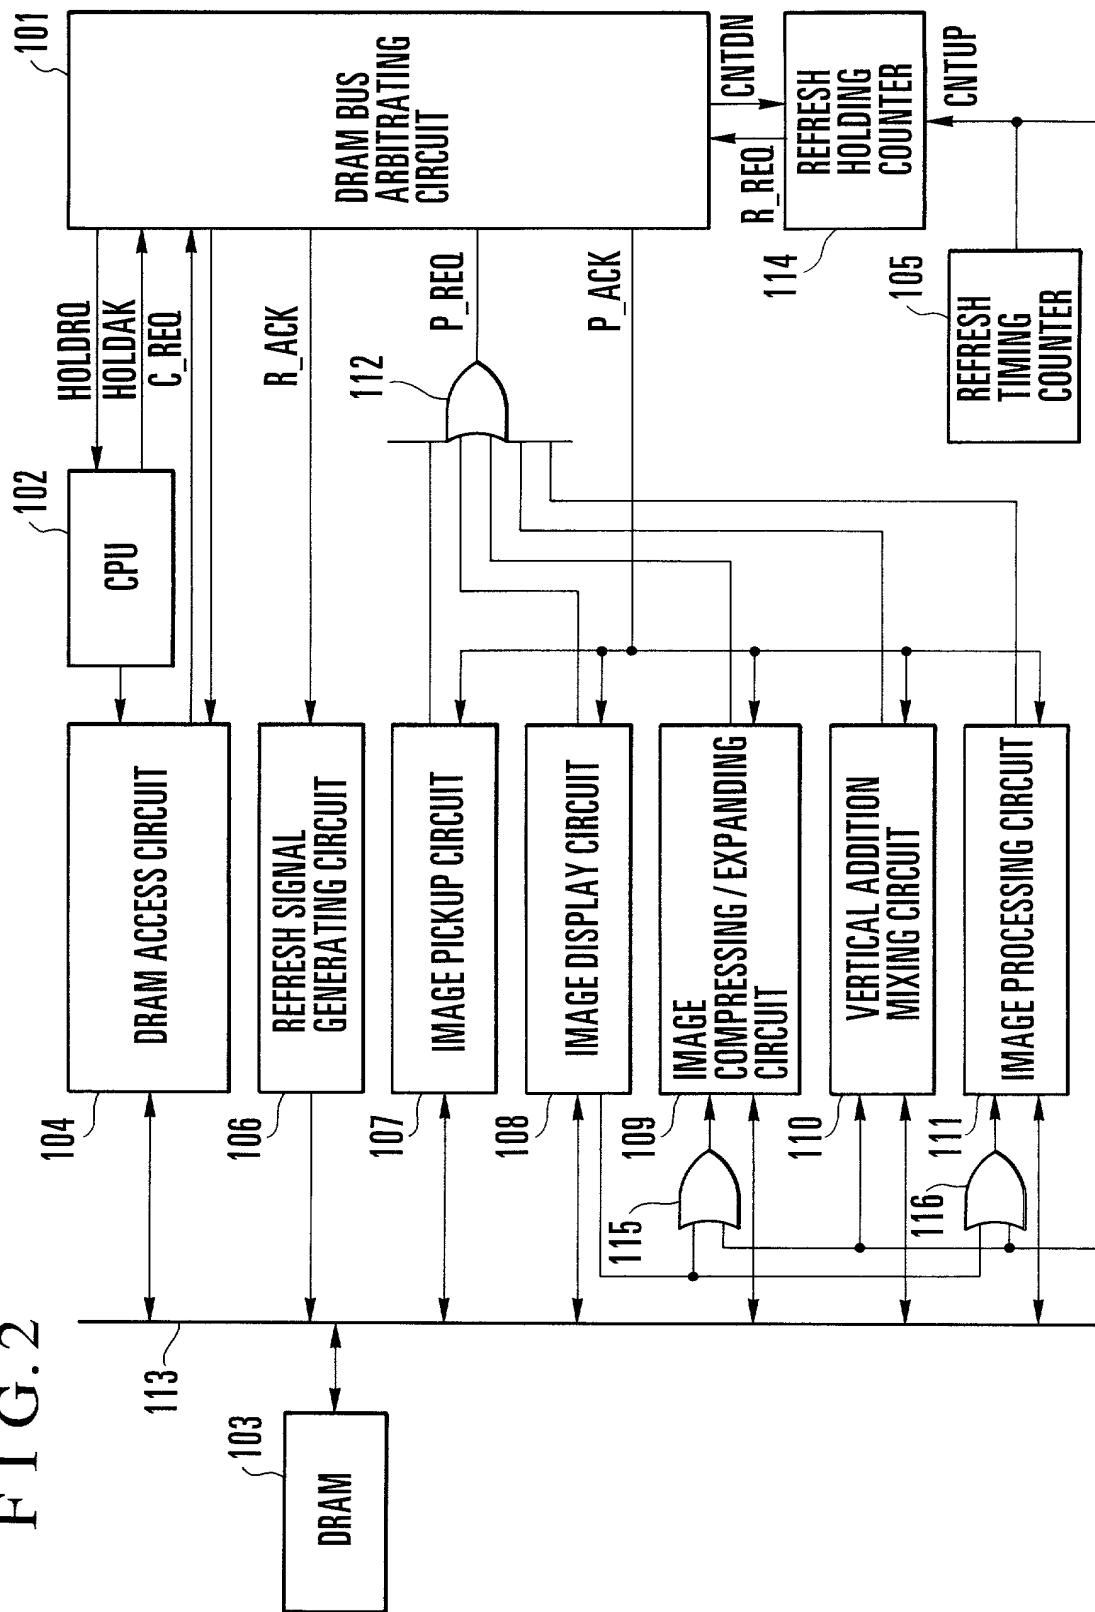

ABSTRACT OF THE DISCLOSURE

In order to reliably execute various kinds of image processing while reliably performing a refresh operation, during the execution of a refresh process for a storage element which stores image data, a first process using the storage element and a second process using the storage element, access to the storage element is arbitrated so that the first process takes priority over the refresh process and the refresh process takes priority over the second process. In addition, in order to reduce the refresh rate of the storage element to the minimum necessary rate to reduce power consumption and to enhance the speeds of other processes, during the execution of a refresh process for refreshing the storage element which stores image data and a process for processing the image data by performing writing of the image data into the storage element or reading of the image data from the storage element, the manner of the refresh process is switched according to the contents of the image data processing process.
